ABSTRACT

REETIKA THAKUR. A methodology to account for seasonal population shifts in North Carolina. (Under the direction of Dr. JOHN HILDRETH and DR. NICOLE BARCLAY.)

Seasonal population has a widespread impact on economic, political and environmental aspects in a region. Since the variation of seasonal population is not constant throughout the country, it is essential to assess the population shifts at local levels. This study introduces the concept of “equivalent residents” as a unit of measurement which represents visitor equivalencies to permanent residents and hence, assesses population shifts at the county level in the state of North Carolina. The adopted methodology utilized sales tax data by the North Carolina Department of Revenue and the permanent population data as certified to the Secretary of Revenue by the State Budget Officer to calculate the number of equivalent residents. This was calculated for each county on a monthly basis for five-year period (2012-2016). The results were then analyzed in terms of magnitude, geographic region and seasonality at county, regional and state level. The study concluded that on an average, the proportion of equivalent residents to permanent residents in North Carolina across five years is 0.11, with the coastal region experiencing maximum equivalent residents influx followed by the mountains and the piedmont region. It was also noted that the population influx of equivalent residents is not constant throughout the year and hence, peak and off peak seasons of each county were defined. 80% of the counties in North Carolina encounter seasonality with the most prominent season being summer season. The study highlights the need to assess seasonal population influx in North Carolina for the efficient allocation of funds and accurate distribution of resources throughout the state.

ACKNOWLEDGMENTS

I would first like to express my sincere gratitude to my thesis advisors Dr. John Hildreth and Dr. Nicole Barclay of the Construction and Facilities Management department at University of North Carolina for the useful comments, remarks, motivation and constant engagement through the learning process of this master's thesis. They consistently allowed this paper to be my own work but steered me in the right the direction whenever they thought I needed it.

I would also like to acknowledge Dr. Jake Smithwick of the Construction and Facilities Management department at University of North Carolina as the committee member of this thesis, and I am gratefully indebted for his very valuable comments and guidance on this thesis.

Finally, I must express my very profound gratitude to my parents for providing me with unfailing support and continuous encouragement throughout my years of study and through the process of researching and writing this thesis. This accomplishment would not have been possible without them.

CHAPTER 1: PROBLEM STATEMENT

The tourism industry is widely influenced by the seasonal fluctuations of tourist demands. Climatic conditions, traditions, festivals, and human decisions are some of the significant factors contributing to seasonal variations. These fluctuations lead to a rise in traffic congestion, environmental problems, off-season unemployment and resource scarcity (Andriotis 2005). Even though seasonal visitors create excessive strain on the infrastructure and services of the destination, it has been observed that very few efforts have been made for the development of an assessment technique to measure seasonal population on national, state or even local levels. Typically, the positive economic impacts of seasonal migration are discussed while the negative consequences such as the building of facilities (only for a part of the year) by communities to deal with the substantial variation in size are ignored (Happel and Hogan 2002).

Markham et al. (2013) state that for the effective allocation of resources and the delivery of services, assessment of service population (number of people who access goods or services in a location) is crucial. The inefficiency in assessing the extent of such demands affects government agencies at the federal, state and local levels, grants commissions, businesses, and individual service providers. Besides, peak load problems of vehicles and congestion associated with roads can be resolved if the varying population size is accurately predicted (Happel and Hogan 2002).

Every year, a wide range of funds by the government are allocated based on population in an area. For instance, upon the appropriation of funds by the General Assembly to the Department of Transportation for State aid to municipalities, the

appropriated amount is distributed according to State Street-Aid Allocation Law. The law distributes the funds in the following two proportions:

- 75% is based on the percentage proportion of the population of each eligible municipality to the total population of all the eligible municipalities.
- The remaining 25% of the funds based on relative mileage of public streets in compliance with the Act (not constituting State highway system) (Powell Bill).

The allocated funds are then used for the maintenance, repair, and construction, reconstruction, widening, or improving streets. It can be observed that the significant proportion of the funds to the municipality are allocated based on the total population. Thus, it is beneficial to assess the seasonal population accurately in the State of North Carolina at the local level for the efficient and accurate distribution of the funds.

The North Carolina Visitor Profile states that North Carolina is ranked sixth concerning domestic visitation in the US with approximately 46-million trips in 2017. The most popular season to travel was summer (June-August) followed by fall (September-November) and spring (March-May). The winter season experienced the least number of visitors (2017 North Carolina Visitor Profile). The allocation of funds to the NCDOT by the General Assembly of North Carolina as mentioned earlier excludes such temporary or seasonal visitors that could impact the funds allocated to the municipalities. Additionally, this increase in population affects various aspects of local life in the state, such as health services, traffic, street safety and loss of local identity (Rebollo and Baidal 2003).

Despite the widespread effects of tourism on every facet of business and political life, the government or private sector has been unable to assess tourism effectively as tourism is not reported in the Gross National Products Accounts. Researchers have adopted

various methodologies in the past, and the assessment of the seasonal population by analyzing the collected sales tax in an area is the most promising due to the readily available objective database. The other benefit is the availability of tax data at local levels throughout the country (Smith 1989).

NC House Bill 257 Session Law 2017-57 enacted 2018 June included in section 34.17 (b) a provision requiring NCDOT to study how to adjust the formula in G.S. 136-41.1(a) to account for seasonal shifts in municipal populations. The research study stems from developing a methodology to account for the seasonal population in the state of North Carolina at the local level. This study introduces the concept of “equivalent residents” as a unit of measurement which represents visitor equivalencies to permanent residents and hence, assesses population shifts at the county level. It was necessary that the research study assumes similar expenditure patterns for permanent and seasonal residents. For instance, one equivalent resident represents a seasonal resident paying the same amount of tax as by a permanent resident.

The research project assessed seasonal population shifts in the state of North Carolina by:

- Assembling population and monthly sales tax data for NC counties over a five-year period (2012-2016) to establish permanent population parameters
- Utilizing sales tax data for the assessment of monthly equivalent residents at the county level
- Quantifying population fluctuations concerning months/seasons, geographical location and magnitude

- Demonstrating the extent and scope of seasonal shifts in the population of a county
- Analyzing the variation in the number of equivalent residents to permanent residents throughout the state over the five-year period (2012-2016)

CHAPTER 2: LITERATURE REVIEW

2.1 INTRODUCTION

In a region, visitors can have widespread economic, social and physical impacts on communities. They are responsible for an increase in the demand for goods and services and extra stress on the natural environment and physical infrastructure (Smith 1989). Traffic, retail sales, crime, littering and pollution, real estate prices, and local employment are some of the areas affected by visitors (Smith and House 2007).

The visitor population varies throughout the country. There are certain places like New York (NY) experiencing a steady flow of visitors in contrast to areas like Florida and Arizona having visitors only for certain seasons. Hence, it is difficult to predict and meet additional demands generated by these visitors (Smith and House 2007). Assessing population in a geographic area accurately throughout the year can help in predicting the other requirements. The accurate evaluation of the population will also facilitate planning for public service provision, such as local police, fire, water, and infrastructure to the ability to secure population-based funding (Graebert et al. 2014).

Even though tourism has become one of the most significant and fast-growing industries worldwide and has a substantial effect on every business and political life, an objective and easily reproducible method to assess tourist population is not available. The lack of a unified database is the primary barrier faced by all the researchers attempting to evaluate tourism. A centralized database (multi-dimensional, multi-layered, multi-disciplinary database) is a single source of information in a variety of different formats from a variety of various origins (“What is Unified Database”). Such a database facilitates the assessment of tourist population as it is readily available and reliable. A database for

the tourist population is currently unavailable because tourism is not reported in the National Income and Product Accounts (GNP Accounts) and hence, cannot be directly obtained from federal government data. Additionally, not having a universally acceptable definition of tourism throughout the country is a drawback (Trager et al. 1986).

2.1.1 DEFINING SEASONAL POPULATION

Over the years, the factor which has complicated the research studies extensively is the unavailability of a universally accepted definition of tourism (Trager et al. 1986). This research study measures “equivalent residents” which represents seasonal residents having similar expenditure patterns as of permanent residents. Hence, equivalent resident is a unit of measurement adopted by the study to avoid any conflict due to an assumption.

The results of the study assessed visitor equivalencies to permanent population to account for seasonal population shifts in North Carolina. Even though the term “equivalent residents” is adopted, the literature review section will continue to use “seasonal population,” “temporary population,” “tourists” and “visitors” interchangeably as initially used by the respective authors. The type of temporary residents found in the United States are:

- i. Retirees who travel according to preferable seasons
- ii. Families taking long vacations
- iii. Migrant farm workers
- iv. People traveling to and fro from the workplace on weekdays and home on weekends
- v. People taking overnight business trips
- vi. Domestic visitors for pleasure purposes and

- vii. Transients with no permanent address (Smith 1989)

The research study focused primarily on the visitors traveling within North Carolina. According to the North Carolina Visitor Profile (2017), the visitors are addressed as overnight visitor and daytripper. An overnight visitor is defined as the one spending at least one night away from home during travel while a visitor who traveled at least 50 miles one-way from home but did not spend any nights away from home is defined as a daytripper. The visitors in both the categories came to North Carolina for leisure (including visiting friends and relatives, outdoor recreation and entertainment/sightseeing), business (including seminar or another group meeting) and other purposes (2017 North Carolina Visitor Profile).

2.1.2 IMPORTANCE OF ASSESSING SEASONAL POPULATION

The tourism market is growing exponentially as the rural communities are also exploring alternative means of income. The most widely adopted alternative means of income is tourism industry as there has been a noticeable decline in traditional agricultural industries such as agriculture, mining, and forestry over the past three decades (Byrd et al. 2009). The efficient operation of tourism facilities and infrastructure is ensured by the competent and overall understanding of reasons affecting tourism at a particular place. For instance, tourism in Turkey is mainly during the warmer months of the year, and it is essential to assess the seasonality aspect of per person tourist spending to develop and sustain competitive advantage in competitive tourism markets (Koc and Altinay 2007). Similarly, northwest Michigan experiences substantial variation in the seasonal population throughout the year and is a major driving factor of the prevailing economic conditions in the area (Graebert et al. 2014).

Another reason for assessing temporary residents is political. The change in the population of an area due to temporary residents affects the social, economic and environmental conditions which in turn raise the demand for effective public planning at all levels. Hence, demographers should be prepared to meet the increase in demand of the temporary residents (Smith 1989). For instance, there is a land-based hurricane evacuation route based on the permanent population of Monroe County in Florida to escape within 24 hours, but there is no room for a significant seasonal population in that county. During a peak season, the full evacuation could take more than 30 hours according to the estimates (Bialik 2012). Thus, the assessment of the seasonal population can also play a vital role in handling such emergencies.

The allocation of seasonal residents has a massive impact on the distribution of funds by the authorities based on population in an area. For instance, a significant portion of funds in the state of North Carolina are allocated based on the population as stated in the “State Street-Aid Allocation Law” (Powell Bill). A similar trend is observed in the state of Arizona. An accurate estimation of the seasonal population will ease the allocation process as there is a huge difference in the number of summer and winter visitors (Bialik 2012).

2.1.3 PROBLEMS FACED WHILE ASSESSING SEASONAL POPULATION

Despite the growing importance of the seasonal population throughout the country, their size, distribution, and characteristics are still not measured accurately. Permanent residents, or persons for whom a particular state, county, or city is the usual place of residence are generally accounted for in most of the population assessments in the United States (Smith 1989). The decennial census and the annually published rolling average of

the monthly American Community Survey (ACS) are generally used for the estimation of the population (Van Auken et al. 2006). Using a two-month rule wherein the ACS defines the resident as the one living in a unit for two months, or more can enable them to profile seasonal populations. The sample size for the year 2016 was approximately 3.54 million housing unit addresses making its usage limited because of the small sample size (US Census Bureau 2018).

The most significant barrier to the evaluation of tourism as discussed before is the lack of relevant data. The various existing data sources provide information only for certain places and certain types of temporary residents. The tourist data can never be evaluated from federal government data as it is not isolated in the GNP accounts. Also, there is no uniform tourism accounting standard followed by the governmental and private sector entities throughout the United States (Trager et al. 1986).

It is often observed that accommodating the annual influx of residents and adjusting to their eventual exodus is difficult for the seasonal communities (Bialik 2012). Due to the absence of comprehensive census data, several different techniques are adopted by various researchers, but the methods remain imprecise and unreliable (Smith 1989).

2.2 PREVIOUS METHODOLOGIES

The literature states that there are generally two approaches to evaluate temporary populations: (i) Direct and; (ii) Indirect. While the direct approach is based on collected censuses and surveys, the indirect approach focuses on symptomatic variables that reflect the changes in temporary populations.

2.2.1 DIRECT APPROACH

INTRODUCTION

The direct approach uses information directly from temporary residents collected by census and surveys. Residence and travel patterns of an individual are evaluated by recording and analyzing the responses to the asked questions by the researchers (Smith 1989). For instance, metrics such as motivation, income, age, length of stay and spending are documented by conducting periodic surveys of visitors by the travel bureau, Visit Florida. This information is then made available to the local planning councils to help them incorporate season population for the creation of budgets and infrastructure plans (Demographics 2001).

RESEARCH METHODOLOGIES RELATED TO DIRECT APPROACH AND RESPECTIVE FINDINGS

To provide some information relating to the seasonal population, housing data since 1970 has been collected by the decennial census. Housing units that have been used for only during certain seasons are classified as “seasonal,” such as summer homes. It was suggested that the Census Bureau should retain the demographic information of such “seasonal” or vacation home so that the number and characteristics of temporary residents can be analyzed (Happel and Hogan 2002). This method had several limitations:

- the availability of the data was only once every ten years
- the seasonal residents staying in another kind of accommodations were not covered and
- not enough information about the number or characteristics of the persons occupying the units

At the state or local level, mostly direct-approach data collections have been adopted to predict seasonal populations. Florida, Texas, and Arizona are the primary snowbird destination states (warmer states experiencing travelers in the winter season) that have been surveyed by the researchers for their state's winter resident populations. While the statewide household survey collects periodic information about the seasonal residents in Florida (Smith 1989), seasonal residents in the Rio Grande Valley of Texas are surveyed by the researchers at Pan American University (Martin et al. 1987). However, in Arizona, the information about seasonal residents was gathered through the distribution of questionnaires at large snowbird events and a statewide household survey. The above stated direct approaches provide detailed microdata. Even though it is not possible to produce such data by any other secondary source, census and survey methods are not very useful as they are quite expensive and labor intensive. Also, developing statistically valid sampling procedures can be a tedious task (Happel and Hogan 2002).

As the State of Florida experiences more temporary residents than any other state, several researchers have tried to examine temporary migration trends in Florida by using several different techniques. Smith and House (2007) focused on visitors with an extended stay rather than daytime or short-term overnight visitors. Telephone surveys conducted by the Bureau of Economic and Business Research (BEBR) at the University of Florida were collected and used as the primary data for the study conducted by Smith and House (2007). A series of monthly phone calls to homes and hotels in Florida were made and then used to categorize respondents as permanent residents; temporary residents (visitors staying for at least one month) and travelers (permanent residents of Florida who spend at least one month per year elsewhere). Census data used in order to apply the average proportion of

each of these types of visitors to all the housing units and hotels, census. The study resulted in a monthly assessment of the size of each population type. Even though the above-stated study provides reasonable assessments and is convenient to use anywhere, it is expensive and time-consuming like the rest of the discussed approaches. Also, excluding daytime or short-term overnight visitors and other accommodations such as RV parks, limits the applicability of this approach (Smith and House 2007).

SHORTCOMINGS

A count of housing units held for seasonal, recreational or occasional use can be produced by decennial census, but it excludes the number of people staying in RV parks or with families and friends. Thus, it limits the accurate estimation of the seasonal population. Also, the seasonal homes and total populations are evaluated only once every ten years by the census, making it rapidly obsolete (Graebert et al. 2014).

It has been observed that sampling techniques have been adopted by many states to generate tourism data. Subsets of the air and automobile tourist populations are typically surveyed, and through statistical inference, an assessment of the respective population parameters is provided. The focus and reliability of the sampling techniques are limited as they required large funds and committed personnel to capture the relevant number of tourists statewide. Even if both the factors (focus and reliability) are taken care of, the sampling of tourists by county is not possible because it is necessary to sample every intercountry highway in the state for automobile travelers and every major airport for air travelers to capture countywide level tourist population (Trager et al. 1986).

Another concern of all the sampling studies is sampling bias. Sampling bias is a term which refers to a sampling method having some systematically favored outcomes over

others. For instance, telephone sampling may involve a simple random sample selection, but it may miss people who do not have a phone or those having a cell phone that does not have an area code of the region being surveyed. That is why inferences from a biased sample are not as reliable (“Biased Sampling”).

It is important to continually upgrade sampling techniques for evaluating continually changing tourist population over time. Discrete breaks in the data might arise due to continually evolving tourist population and hence, limit the time series analysis on the resultant data (Trager et al. 1986).

2.2.2 INDIRECT APPROACH

INTRODUCTION

‘Symptomatic variables’ which change with the change in population size are used in indirect approaches. Hotel occupancy rates, utility usage, tax receipts, traffic counts, and postal deliveries are examples of symptomatic variables (Rigall-I-Torrent 2010). Ratios, regression analysis, or statistical techniques are used to relate the base data on the symptomatic variables to the number of temporary residents under the indirect approach (Smith 1989).

In addition to the administrative databases, interviewing knowledgeable informants, such as businesspersons or local public officials can help in generating information about seasonal populations (Happel and Hogan 2002). For instance, in Crete (Greece) two methods were adopted to explain the seasonality. First, published and unpublished studies and statistics were collected and analyzed and then, reports were generated by surveying owners/managers of tourism businesses. The results produced from adopting the stated methods were used to determine the variation in tourism throughout the year (Andriotis 2005).

RESEARCH METHODOLOGIES RELATED TO INDIRECT APPROACH AND RESPECTIVE FINDINGS

A research effort began in 1984 by the Arizona State University (ASU) Center for Business Research at the height of the winter season for the evaluation of the snowbirds' population in the Phoenix area. The first survey was limited to evaluating the number of mobile home or RV parks stays in East Valleys locales of Mesa and Apache Junction due to the concentration of a clear majority of snowbird population in these areas. Each winter season, a similar survey about the number of mobile home or RV parks stays has been conducted on a statewide level. In the year of 2000, the survey asked the park owners/managers some additional questions to obtain more insight about this phenomenon. The park owners/managers were asked to categorize all households into one of the following four groups (Happel and Hogan 2002):

- year-round
- winter residents (snowbirds- retirees staying for at least one month in the park during winter season)
- residents visiting for at least one month excluding retirees
- short-term temporary (residing for less than one month)

A more accurate assessment of the snowbird population was obtained along with the information of other types of park residents (Happel and Hogan 2002).

Another instance demonstrating strong seasonality is observed in tourist arrivals and tourism receipts in Turkey. The peak period in Turkey is generally during the warmer months for mainly sun and sea. However, the number of tourists is sparse for the most of the remaining year. To better understand the off-peak period, per person tourist spending was analyzed by Koc and Altinay (2007) in both the peak and off-peak period. The two

stages of the study were: (i) using monthly time series data to investigate the seasonality aspect of per person tourist spending empirically; (ii) segmenting the inbound tourists based on their level of expenditures after analyzing the seasonality findings. The study did indicate that there is no consistency in a seasonal pattern throughout the sample period. Hence, the seasonal model is stochastic. However, the major drawback of this study was lack of availability of monthly data regarding various aspects of tourism activities such as income levels, types of transportation used, age groups, etc. (Koc and Altinay 2007)

Assessment of tourist expenditures by tax collection data is another technique of evaluating the seasonal population. For instance, taxable sales data were used in Florida for the evaluation of seasonal visitors. The information was sorted by month and by county from the year 1980 to 1985 (Trager et al. 1986). The applied taxable data was gathered from the Florida Department of Revenue. The obtained payable data was adjusted over time to account for four significant factors; (i) changes in legislation affecting taxable sales; (ii) growth in the permanent population; (iii) changes in economic conditions; and (iv) changes in the daily expenditure patterns of tourists as they might cause fluctuation in taxable sales data. The month with the lowest level of adjusted taxable sales was assumed to be the one with no visitors while the deviations in monthly adjusted taxable sales with the lowest level were due to the visitors. The tourist expenditure data was gathered from surveys conducted by the Florida Division of Tourism. Monthly assessments of the average daily number of visitors were calculated by dividing the adjusted taxable sales deviations by average monthly tourist expenditures (Smith 1989).

Data from the Wisconsin State Department of Revenue was used for a study in Door County to assess the size of the seasonal population in the county. It was found that

by dividing the total sales in Door County by the statewide average share of sales, the number of people appeared to be double of that of the actual permanent population. The study concluded that the excess of people must constitute visitors to the County. The study had two improbable assumptions: (i) the average Door County resident spends precisely what the average Wisconsin resident spends and, (ii) the visitors pay the same amount as ordinary residents in a year. At the border of the county, a traffic counter was used to assess the monthly variation in vehicles belonging to seasonal visitors. The evaluations of visitors throughout the year were carried by subtracting the least number of vehicles from the total number of vehicles passing through the traffic counter. The least amount of vehicles in a year was considered to be the resident vehicles. (Lamb, 2010). The critical advantage of all the above-stated methodologies is the readily available and repeatable data.

SHORTCOMINGS

In spite of all the advantages, indirect methods also have some disadvantages. Except for the changes in temporary residents, the symptomatic variables may get influenced by the effects of other factors. This might lead to a change in the relationship between temporary residents and symptomatic variables over time. There is a possibility that the assumptions regarding base relationships may not be valid. It is almost never possible to predict a complete count of the number of temporary residents in the base year. Therefore, it is necessary that the base-year relationships must be based on special censuses or surveys, or solely on assumptions regarding the number of temporary residents (Smith 1989).

2.3 CONCLUSION

The practical and accurate assessment of the seasonal population is beneficial to several economic and political situations. There are mainly two approaches adopted by researchers to predict seasonal population variation trends; (i) direct and (ii) indirect. The one significant advantage that the indirect approach has over the direct approach is that it is convenient to apply at the local level at frequent intervals for a relatively little cost. Extensive data collection efforts are required in the direct approach while the indirect method relies on readily available data. The only condition is those base relationships should have been established for the analysis of the data. Even though the direct method is extensive both concerning finance and labor, there is no other way of collecting detailed microdata. Hence, it seems logical to combine both the approaches for the creation of an efficient technique to evaluate the seasonal population (Smith 1989).

Thus, the research study applied a methodology having a readily available and repeatable data on an annual basis to assess the seasonal population of North Carolina in each county. For this purpose, the seasonal population was defined, and its impacts were discussed in depth to have a clear understanding of the prevailing situation. The seasonal population of counties of the state of North Carolina were then assessed by using monthly sales tax data. The assessment might also help to account for seasonal population shifts in distributing Powell Bill allocation funds. The integration of direct and indirect approach was adopted to assess for the merits of both the techniques.

CHAPTER 3: OBJECTIVES AND DESIRED OUTCOMES

The objective of this research was to assess the seasonal fluctuations of equivalent residents in each county of North Carolina. The assessment is essential for the effective implementation of government policies based on the population. The accurate evaluation will also help in resolving the issues related to environmental damage and resource scarcity.

The resulting data for each county was assessed to determine the scope and magnitude of seasonal equivalent residents' changes regarding:

- The magnitude of the total annual equivalent residents to North Carolina and each county – the total annual equivalent residents of each county were calculated by adding the monthly equivalent residents, and then the magnitude was determined concerning the proportion of equivalent residents to the total permanent population. The detailed calculations to assess the equivalent residents on a monthly basis are depicted in the methodology section.
- The geographical distribution of equivalent residents throughout the five year period – the counties were then grouped according to the geographical regions, and comparison was made to analyze the variations through five year period (2012-2016).
- The existence of seasonality – the equivalent residents were classified according to four seasons, i.e. winter, spring, fall and summer, and seasonality was determined at the county, geographic and state level.

The research study might also help in reviewing the existing Powell Allocation Bill. As 75% of the street aid allocations are based on the total population of a municipality in

a year, the evaluated equivalent residents might not directly address the existing issue in the bill but will provide the much-needed perspective on the seasonality in North Carolina area.

CHAPTER 4: METHODOLOGY

The methodology of this research study was developed to assess equivalent residents in each North Carolina county to account for seasonal population shifts. The term equivalent residents is a unit of measurement used to define visitor equivalencies concerning permanent residents. The monthly evaluation of equivalent residents at the county level will help in detecting the extent of seasonality as well as quantifying population fluctuations concerning months/seasons. The methodology aimed to assess the equivalent residents utilizing monthly sales tax data published by the North Carolina Department of Revenue (NCDOR).

The selection of database for the methodology was focused considering specific characteristics. The data should:

- Be readily available without significant time lag (by focusing on monthly collectible/generated data) – the primary objective of the research study was to predict the seasonality in North Carolina concerning equivalent residents. Since the aspect of seasonality is recurring and continually evolving, it is beneficial to have data that is readily available and does not have a significant time lag. The North Carolina Department of Revenue (NCDOR) publishes sales tax data every month for each county. This data was a primary source in this research study as it is credible and readily available.
- Be attributed to specific geographic areas (counties) – the accurate prediction of the seasonality throughout the state is only possible if the effects are observed at the local levels. The sales tax data generated by NCDOR at the county level adheres to the objective of the research study.

- Not be highly responsive to factors extraneous to population changes – it is essential that the data remains unaltered by the elements not affected by the population changes. The data responsive to extraneous factors might affect the precision in predicting the results of the study. The adopted methodology assessed the population changes utilizing collected sales tax data. The adopted formula to assess the equivalent residents remains unaffected by factors such as inflation and political reforms.

Such a set of data will not only ensure that the methodology is readily repeatable on an annual basis but also ease the implementation of the results extensively. The collection and distribution reports of the sales taxes by the NCDOR includes sales and use tax levies for Articles 39, 40, 42, 43, 44, 45 and 46. Out of these articles, Article 39 is the purest form of tax and levied by every county in the state whereas all the other articles are just collected by selective counties. Hence, the research study utilized the sales taxes under Article 39.

The research approach is an amalgamation of the direct and indirect method to quantify the changes in equivalent seasonal residents in North Carolina counties. The direct portion of the methodology is utilizing the permanent population data at the county level as certified to the Secretary of Revenue by the State Budget Officer. The other source of data representing the indirect method of the research study is monthly sales tax data published by the NCDOR. The monthly equivalent residents could only be evaluated at the county level due to the unavailability of a database addressing municipalities directly. The sales taxes are collected and distributed at the county level first, and then the counties

distribute the taxes to the municipalities utilizing distribution percentages which are explained in detail in the next section.

The objective of quantifying the equivalent residents on a monthly basis at the county level was accomplished by first collecting the permanent resident population and the total monthly sales taxes. It was assumed that the month with the least sales taxes is wholly due to permanent residents so that the equivalent seasonal residents can be assessed by apportioning the remaining sales taxes. To reduce the ambiguity in the assumption, the taxes over and above the minimum are adjusted to account for both the variations in the taxes from permanent and equivalent residents.

After allocating the sales taxes to the equivalent residents, the number of equivalent residents were calculated by assuming similar expenditure patterns for both the permanent and equivalent residents. This further explains the reason for introducing the term “equivalent residents” in the research study. The objective of the research was not only to find the number of equivalent residents but to also quantify population fluctuations to months/ seasons, geographical location and magnitude. Hence, the results were analyzed and discussed in depth in the later sections to address the concept of seasonality throughout the state.

4.1 COMPILATION OF THE PERMANENT POPULATION DATA BY COUNTIES

The direct portion of the methodology was to use the data of permanent county population as certified to the Secretary of Revenue by the State Budget Officer. Therefore, the first step included a collection of permanent county population data based upon the most recent (for the year 2012-2016) annual estimates of population as certified to the Secretary of Revenue by the state demographer with the Office of the State Budget and

Management. The permanent population data was collected for each of the 100 counties in North Carolina. For instance, the permanent population of Buncombe County, North Carolina for 2016 was 470,941. The research study predicts the population over and above the permanent population concerning equivalent residents. Hence, the permanent population data is a base for the adopted methodology.

4.2 COLLECTION AND COMPILATION OF RELEVANT MONTHLY SALES TAX DATA

The indirect portion was to use the Local Sales and Use Tax collections, and distributions reported monthly by the North Carolina Department of Revenue to evaluate the equivalent residents in each county. Local Sales and Use Tax collections, and distributions declared by the NC Department of Revenue were collected for the most recent five fiscal years (FY12 through FY16). These accumulated distributions include Sales and Use Tax levies for Articles 39, 40, 42, 43, 44, 45, and 46. Out of these only Articles 39, 40 and 42 are levied by all 100 counties in the State (“Basics of North Carolina Local Option Sales Taxes”). Article 39 was used for this research study because it is distributed by the point of sale and is the purest form of sales tax as it was the original local option sales tax authorized in 1971. Article 40 and 43 sales taxes are distributed on a per capita basis and do not directly reflect the population (both permanent and equivalent residents) from which it is collected.

The sales taxes collected are listed separately under Article 39 for each county. The raised taxes by the department are further divided among municipalities after deduction of “cost of collection.” The county commissioners distributes the taxes in one of the two bases when they levy the tax (“State-Collected Local Taxes: Basis of Distribution” 2017).

- i. Population Distribution: The distribution of the proceeds will be based on the total population of county and municipalities in case the county commissioner chose population distribution. The distribution of the tax to each unit is on per capita basis.
- ii. Ad Valorem Distribution: When the selected method is ad valorem, the distribution of the proceeds between the county and municipalities will be in proportion to the total ad valorem taxes (in proportion to the estimated value of the goods or transaction concerned) levied by each of the counties.

The NC Department of Revenue publishes percentage share of distribution for each municipality in a county based on both population and ad valorem. The bases of distribution of the proceeds for 57 counties is based on ad valorem while others are based on population. The percentage share of distribution for the Buncombe County in 2016 on the bases of population and ad valorem is represented below to demonstrate the variation in both the percentages.

Table 1: Percentage share of distribution of collected sales taxes for each municipality in Buncombe county, 2016

Municipality	Population	% Share of Distribution	Ad Valorem Levies	% Share of Distribution
BUNCOMBE	254,836	69.50%	\$ 203,009,002	75.31%
ASHEVILLE	90,918	24.79%	\$ 54,568,786	20.24%
BILTMORE FOREST	1,400	0.38%	\$ 2,477,587	0.91%
BLACK MOUNTAIN	8,384	2.28%	\$ 3,809,457	1.41%
MONTREAT	791	0.21%	\$ 960,327	0.35%
WEAVERVILLE	3,833	1.04%	\$ 2,808,627	1.04%
WOODFIN	6,484	1.76%	\$ 1,899,185	0.70%
TOTAL	366,646	100%	\$ 269,532,971	100%

The NC Department of Revenue publishes the similar share of distribution of collected sales taxes to the municipalities every year for all the counties.

While the NCDOR distributes the funds to the eligible municipalities based on these percentage shares, the research study was unable to utilize these percentages for estimating equivalent seasonal residents. This is because these distributions are published annually based on the data of the prior year and hence, there is no way to break down the collected tax on the municipality level on a monthly basis. Using the annual distributions published by the NCDOR resulted in similar seasonal fluctuation trends throughout the municipalities in a county and defeats the purpose of accounting variations in the equivalent residents on a monthly basis. That is why the monthly collected sales tax for each county from 2012 to 2016 under Article 39 will be used as the basis of the research to predict the seasonality at the county level. The monthly sales tax collection of Buncombe County, North Carolina for 2016 is tabulated below for reference.

Table 2: Sales tax collection under Article 39 of Buncombe county, North Carolina for 2016

Month	Collected sales taxes
January	\$ 4,665,694.44
February	\$ 3,116,603.21
March	\$ 2,073,972.22
April	\$ 4,090,818.65
May	\$ 4,137,482.13
June	\$ 4,066,145.47
July	\$ 4,413,868.47
August	\$ 3,021,975.52
September	\$ 4,054,152.66
October	\$ 4,281,198.36
November	\$ 4,524,077.05
December	\$ 4,258,943.48

4.3 ASSESSMENT OF THE SEASONAL EQUIVALENT RESIDENTS

It was necessary to assume that the month with minimum collected tax within each county reflects the permanent population. The minimum collected tax was then adjusted to calculate tax paid by the residents every month throughout the year. The adjustment assumes that the resident tax in addition to the minimum will vary in proportion to the minimum resident tax by the total collected tax. The excess tax was defined as the sales tax collected from equivalent residents and was used to assess variation in equivalent residents on a monthly basis in each county. Data over the five-year period was analyzed to consider annual variations appropriately.

The methodology developed a formula for calculating the equivalent residents by first finding the minimum monthly sales tax in a year (R) of each county and then calculating the difference between the minimum and total taxes (O) for the remaining months. Even though the study assumed that the minimum monthly tax wholly represents the tax from the permanent resident, it does not assume that the spending of permanent residents is constant throughout the year. That is why, the excessive monthly tax was divided into two portions, (i) adjusted sales tax from permanent residents (R_o) and (ii) sales tax from equivalent residents (N). The adjusted sales tax (R_o) was then calculated by assuming that the variation of the sales tax from residents in the remaining tax (O) are in proportion to the minimum sales tax (R) by the total tax ($R+O$) in a month, i.e., $R_o = O (R / R + O)$. Further, sales tax by the equivalent residents (N) was calculated by subtracting the adjusted sales tax (R_o) from the total remaining sales tax (O). The number of equivalent residents were then calculated by dividing the sales tax (from equivalent residents) by the monthly tax paid per resident.

The following formula was adopted for the calculation of equivalent residents:

R = Minimum sales taxes in a year

R_o = Adjusted sales taxes (From permanent residents)

N = Sales taxes from equivalent residents

O = Difference between the total and minimum sales taxes on a monthly basis

PR = Permanent Resident population

PT = Equivalent residents

$$O = R_o + N \quad \dots\dots\dots (i)$$

$$R_o = O (R / R + O) \quad \dots\dots\dots (ii)$$

$$PT = N / [(R + R_o) / PR]$$

$$= (N * PR) / (R + R_o)$$

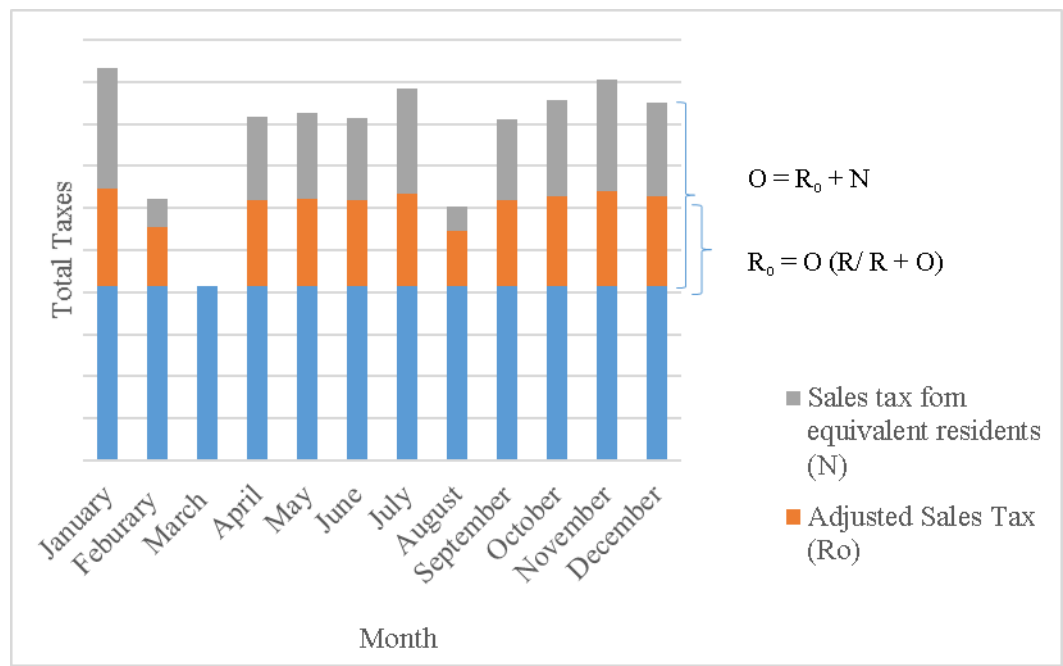

Figure 1: Graphical description of the adopted formula for the calculation of equivalent residents

4.4 ANALYSIS OF THE RESULTS

The detailed calculations and analysis of results from applying the methodology is discussed in this section. Firstly, continuing the example of Buncombe County the calculations for the equivalent residents are represented in the Table 3. The permanent population certified by the Office of State Budget and Management (OSBM) of Buncombe County for the year 2016 was 470,941 persons.

Table 3: Calculated values for equivalent residents per month of Buncombe county, 2016

Month	Difference between the total and minimum sales taxes on a monthly basis (O)	Adjusted sales taxes (From permanent residents) (R _o)	Sales taxes from equivalent residents (N)	Equivalent Residents (PT)
January	\$ 2,591,722.22	\$ 1,152,059.99	\$ 1,439,662.23	161,150
February	\$ 1,042,630.99	\$ 693,828.36	\$ 348,802.63	45,507
March	-	-	-	0
April	\$ 2,016,846.43	\$ 1,022,505.23	\$ 994,341.20	115,959
May	\$ 2,063,509.91	\$ 1,034,363.92	\$ 1,029,145.99	119,560
June	\$ 1,992,173.25	\$ 1,016,124.98	\$ 976,048.27	114,061
July	\$ 2,339,896.25	\$ 1,099,461.81	\$ 1,240,434.44	141,150
August	\$ 948,003.30	\$ 650,611.66	\$ 297,391.64	39,415
September	\$ 1,980,180.44	\$ 1,012,995.70	\$ 967,184.74	113,140
October	\$ 2,207,226.14	\$ 1,069,262.70	\$ 1,137,963.44	130,734
November	\$ 2,450,104.83	\$ 1,123,201.33	\$ 1,326,903.50	149,868
December	\$ 2,184,971.26	\$ 1,064,012.64	\$ 1,120,958.62	128,996

The results were then analyzed to fulfill the objectives of the research by calculating:

- The magnitude of the total annual equivalent residents to North Carolina and each county

The total annual equivalent residents of each county were calculated by adding the monthly equivalent residents, and then the magnitude was determined

concerning the proportion of equivalent residents to the total permanent population. The proportion of equivalent residents to the total permanent population each year was then averaged to draw conclusions on the equivalent resident influx each year and then throughout the five years. .

- The geographical distribution of equivalent residents throughout the five-year period (2012-2016)

The counties were then grouped according to the geographical regions (Piedmont, the Coastal Plains and the Mountains), and comparison was made to analyze the variations through the five-year period (2012-2016). Table 4 lists the counties according to the respective geographical region. The average monthly equivalent residents for each county on a yearly basis were then summed up to analyze the variations in the geographic region.

- The seasonality of population changes

The equivalent residents were sorted according to four seasons, i.e. winter (Dec- Feb), spring (March-May), summer (June-Aug) and fall (Sept-Nov) in a particular year and seasonality was determined at the county, geographic and state level.

The study defines three levels of seasonality as shown in Table 5 below.

Table 5: Criteria to define seasonality

High Seasonality	Same season has maximum number of equivalent residents across five years (2012-2016) for at least 3 of 5 years and the highest season is 12% more than the second highest season.
Low Seasonality	No particular season has maximum number of equivalent residents across five years (2012-2016) for at least 3 of 5 years but the highest season is 12% more than the second highest season.
No Seasonality	No season has maximum number of equivalent residents across five years for at least 3 out of 5 years from five year period (2012-2016) and the highest season is not more than 12% from the second highest season.

The explained methodology was applied to each county of NC and the results were observed closely to draw the required conclusions as per the objectives of the research. The detailed calculations and results for each county are attached in the Appendices of the document.

CHAPTER 5: RESULTS AND DISCUSSIONS

This section contains the detailed description and discussion of the results obtained after applying the methodology to each county of North Carolina.

The focus of the research study was to account for seasonal equivalent resident shifts in North Carolina. The study evaluated the variation of equivalent residents at the county level to predict the seasonality throughout the state. The percentage distribution of permanent population and equivalent residents in the state does not follow a similar population influx pattern. The inconsistency in the trends is because the concentration of equivalent residents is influenced by several other factors, such as weather, geographic region, holiday season, business opportunities, significant events like music concerts, and tourist attractions as stated in the literature.

The study further assessed the seasonal patterns of equivalent residents. For instance, summer is the most visited season in the mountains and the coastal plains of North Carolina. Most of the counties experienced the most significant number of equivalent residents in the summer season.

5.1 MAGNITUDE OF EQUIVALENT RESIDENTS IN EACH COUNTY

5.1.1 COUNTY LEVEL

The analysis of the permanent and equivalent resident population throughout the state was essential to conclude the effect of seasonality accurately. The average monthly equivalent residents of each county are calculated on a yearly basis, and then the magnitude is determined concerning the proportion of equivalent residents to the total permanent population (Tables 6, 7 and 8). It can be observed that the percentages are not consistent every year; hence, it is essential to find the average to analyze the proportion of

the population influx of equivalent residents across five-years. The county with the maximum proportion of average yearly equivalent residents to permanent residents is Currituck followed by Hyde, Forsyth, Dare, Clay, and Jones. Even though Forsyth and Clay averaged out to be the counties with greater proportion, it was only due to a higher number of taxes in one particular year. This is the reason that the assessment of equivalent residents is essential on a yearly basis to accurately predict the frequency and magnitude of the equivalent residents on the county level.

Table 6: Percentage of average monthly equivalent residents to total residents at county level for counties in coastal plains region

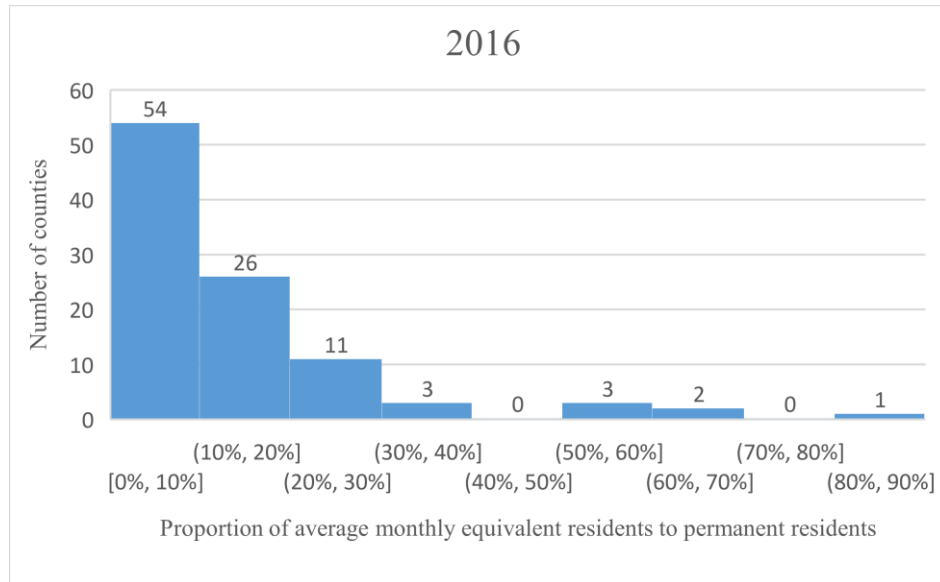

Figure 6: Frequency distribution of proportion of average monthly equivalent residents to permanent residents, 2012

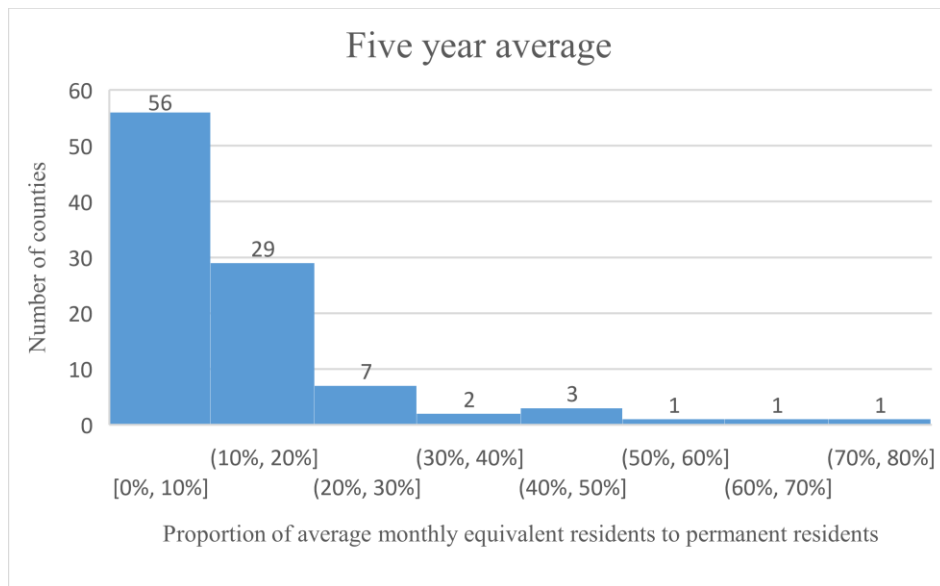

Figure 7: Frequency distribution of proportion of average monthly equivalent residents to permanent residents over five years (2012-2016)

It can be observed that the maximum number of counties, each year lie in the range of 0-10% throughout each year and the five-year period. This implies that the magnitude of equivalent residents is significant and needs to be addressed by the concerned authorities. The magnitude is significant because even if the contingency plan does include

5% of permanent residents above the total, the actual population influx of equivalent residents remains unevaluated. It can be observed that none of the counties experience a more significant number of average monthly equivalent residents than that of permanent residents throughout the five years (2012-2016). The average percentage of monthly equivalent residents to the permanent residents is 11%. It is noted that the counties have a different magnitude of equivalent residents throughout the state and it is necessary to evaluate the equivalent residents at the local level accurately. The evaluation of these equivalent residents in North Carolina will help in the effective allocation of resources and the delivery of services. Also, peak load problems of vehicles and congestion associated with roads can also be resolved (Happel and Hogan 2002).

Another benefit of evaluating the equivalent residents is political. The excess population in an area affects public planning at all stages, and it is beneficial for the demographers to meet the increasing demand (Smith 1989). The results from Table 6 can prove to be advantageous while sorting out the counties that need attention and smoothen the planning and allocation process.

The calculations depicted the abnormally higher proportion of Orange County due to a higher tax difference between the minimum tax and the rest of the taxes in a year. The ambiguity in the tax data could lead to incorrect results and conclusions. This is why Orange County was included while summarizing the results.

5.1.2 REGIONAL LEVEL

The magnitude of population influx of equivalent residents was then analyzed according to three geographic regions, (i) Piedmont, (ii) Coastal Plains and (ii) Mountains as mentioned in Table 4. The proportion of average equivalent residents to the average permanent residents in a region are then calculated to assess the magnitude of equivalent residents at the regional level over a five-year period as shown in Table 9.

Table 9: Percentages of average monthly equivalent residents to total residents at regional level through 5 years

Region	2012	2013	2014	2015	2016	Average
Coastal Plains	12%	14%	16%	12%	16%	14%
Mountains	11%	14%	14%	13%	16%	14%
The Piedmont	12%	13%	10%	7%	8%	10%

The results state that the equivalent residents are distributed throughout the state, and it is essential to analyze each geographic region in detail to assess the magnitude of the equivalent residents. It can also be concluded that the population influx of equivalent residents across five years does not vary significantly. The magnitude of average monthly equivalent residents is maximum in coastal plains followed by mountains and the piedmont region. Even though the number of counties in mountains is less than that of coastal plain, the proportion of average monthly equivalent residents to total residents is higher in mountainous region. This implies that no particular region can be given preference over the other when considering the magnitude of the equivalent residents based on the number of permanent residents in an area.

5.1.2 STATE LEVEL

It is also essential to assess the magnitude of the equivalent residents at the state level to assess the overall impact. The proportion of average equivalent residents in North Carolina to the average population of the state is 0.11 as shown in Table 10. That means equivalent residents are 11% in magnitude as compared to the permanent residents. Specifically, the approximate population of North Carolina is 10 million and 11% of the total permanent residents is 1.1 million. This sheer magnitude directs to the importance of assessing equivalent residents in an area. There are 1.1 million equivalent residents on average which remain unassessed every year. This affects the region at economic, political and environmental levels as stated in the literature.

Table 10: Percentages of average monthly equivalent residents to total residents at state level through 5 years

State	2012	2013	2014	2015	2016	Average
North Carolina	12%	13%	12%	8%	11%	11%

5.2 THE GEOGRAPHICAL DISTRIBUTION OF EQUIVALENT RESIDENTS THROUGHOUT THE FIVE-YEAR PERIOD.

The counties in each geographical region, the Piedmont, the Coastal Plains and the Mountains were then analyzed to compare the variations through five-year period (2012-2016). The sum of the average monthly equivalent residents geographically are represented in Figures 8-10.

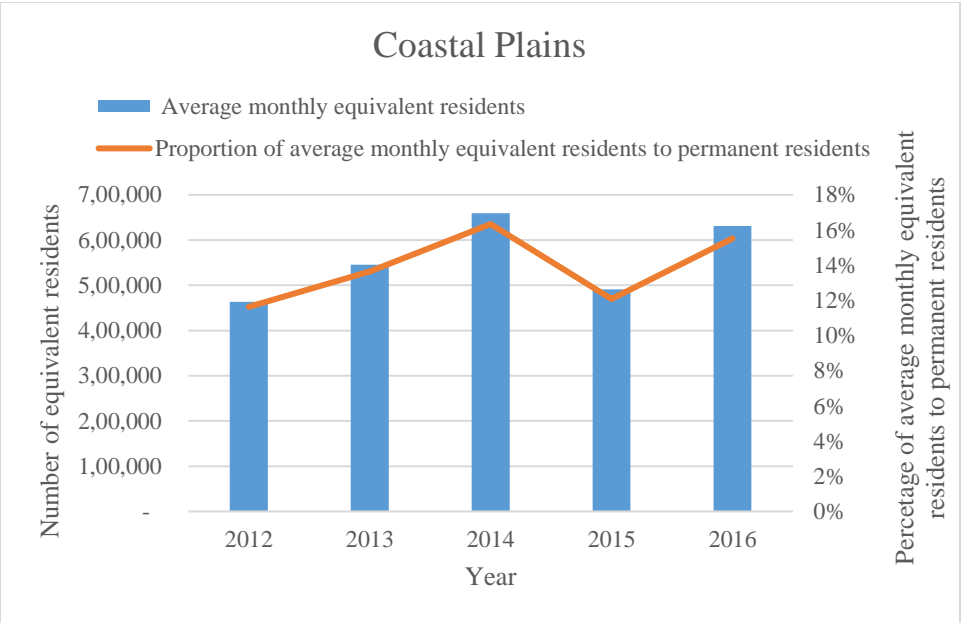

Figure 8: Magnitude and distribution of equivalent residents in coastal plains region

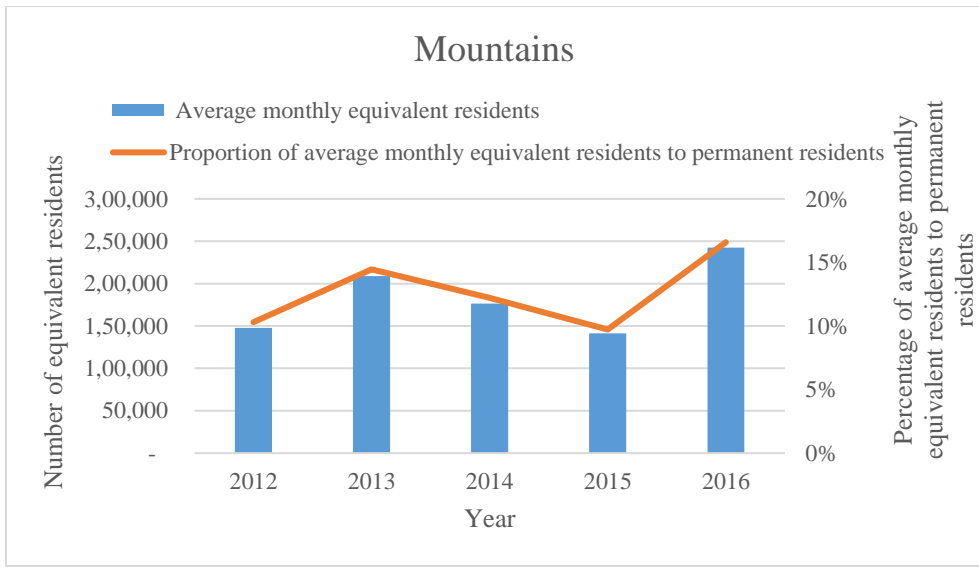

Figure 9: Magnitude and distribution of equivalent residents in mountainous region

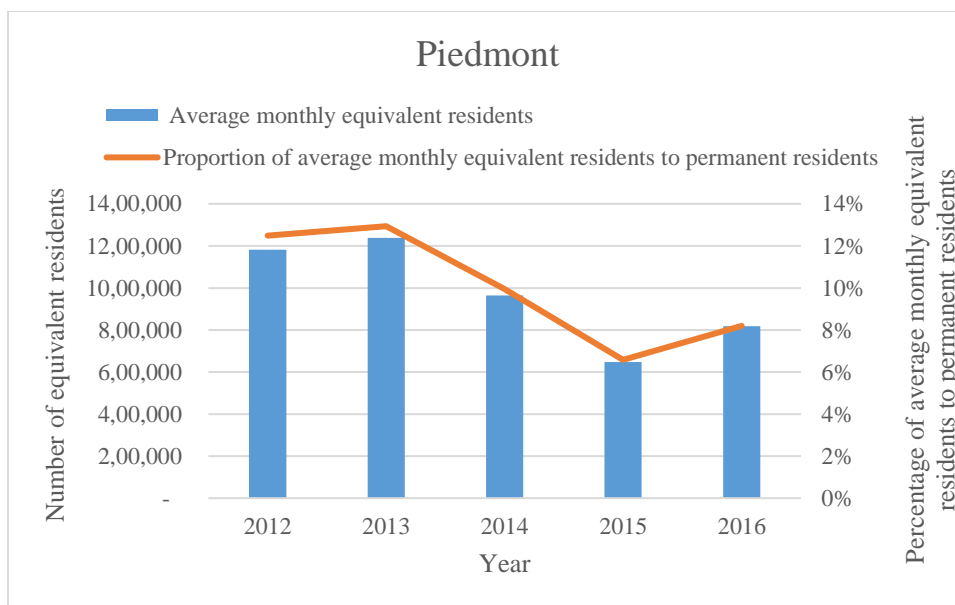

Figure 10: Magnitude and distribution of equivalent residents in piedmont region

Figures 8-10 depict the variation of average equivalent residents in the geographic region across 5 years (2012-2016) with the percentage distribution of equivalent residents to permanent residents on a yearly basis. It can be observed that the average is not constant every year and the maximum proportion of average monthly equivalent residents to permanent residents vary from region to region. The region experiencing maximum population influx is Piedmont region but the magnitude of equivalent residents to permanent residents is maximum in mountainous region. This reiterates the need to compare both the magnitude of equivalent residents and the proportion of equivalent residents to permanent residents to clearly analyze the intensity of population influx of equivalent residents in a region.

The average equivalent residents were also calculated at state level and the variation is assessed to study the impact at broader level (Figure 11). It can be observed that the proportion of average monthly equivalent residents to permanent residents is 11%

making it significant. Even though the average proportion varies at county and regional levels, the magnitude of equivalent residents was essential to analyze the extent of the problem and then evaluated at regional and local levels to highlight the areas which need attention.

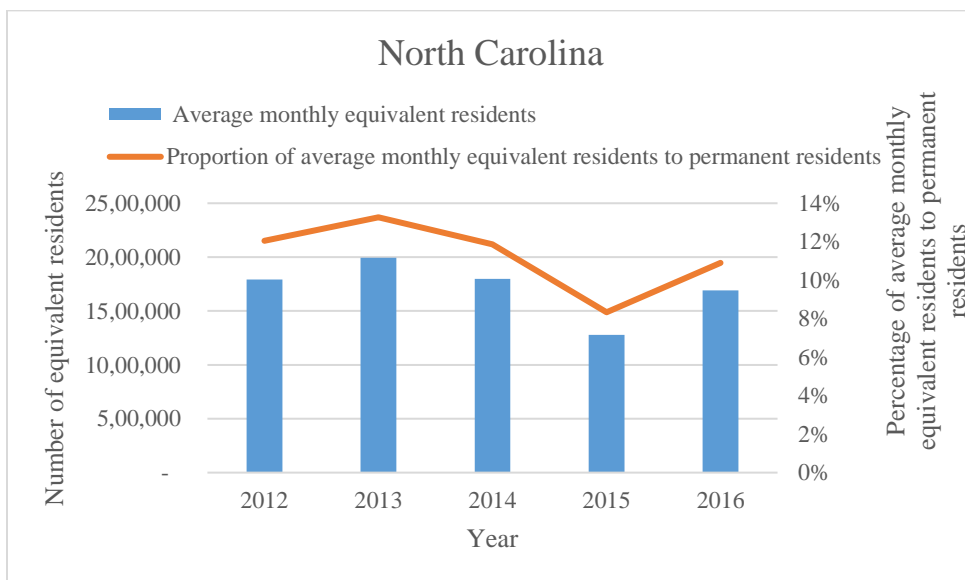

Figure 11: Magnitude and distribution of equivalent residents in North Carolina

5.3 SEASONALITY

The equivalent residents are sorted according to four seasons i.e. winter (Dec-Feb), spring (March-May), summer (June-Aug) and fall (Sept-Nov) and seasonality is determined at county, geographic and state level.

The study defines three levels of seasonality as high, low and no seasonality as mentioned in Table 5.

5.3.1 COUNTY LEVEL

Figure 7 depicts seasonality throughout the state at county level using the criteria in Table 5 and it can be concluded that seasonality does exist. The value that is not

assigned is of the Orange County which is excluded because of unusual tax data for this county.

Table 11: Seasonality at county level

HIGH SEASONALITY	LOW SEASONALITY	NO SEASONALITY
ALEXANDER	ALAMANCE	BERTIE
ALLEGHANY	ANSON	CABARRUS
ASHE	BEAUFORT	CALDWELL
AVERY	CAMDEN	CASWELL
BLADEN	CHOWAN	CHATHAM
BRUNSWICK	CLEVELAND	CLAY
BUNCOMBE	CUMBERLAND	COLUMBUS
BURKE	DAVIDSON	EDGECOMBE
CARTERET	DURHAM	GASTON
CATAWBA	FRANKLIN	HARNETT
CHEROKEE	GRANVILLE	HAYWOOD
CRAVEN	GUILFORD	LEE
CURRITUCK	HALIFAX	MACON
DARE	HOKE	MARTIN
DAVIE	JOHNSTON	ORANGE
DUPLIN	JONES	PERSON
FORSYTH	MCDOWELL	RANDOLPH
GATES	MOORE	TYRRELL
GRAHAM	NASH	WAKE
GREENE	NORTHAMPTON	WATAUGA
HENDERSON	PASQUOTANK	
HERTFORD	PERQUIMANS	
HYDE	PITT	
IREDELL	RICHMOND	
JACKSON	ROCKINGHAM	
LENOIR	SAMPSON	
LINCOLN	SCOTLAND	
MADISON	STANLY	
MECKLENBURG	STOKES	
MITCHELL	SURRY	
MONTGOMERY	UNION	
NEW HANOVER	WASHINGTON	
ONSLow	WILKES	
PAMLICO		
PENDER		
POLK		
ROBESON		
ROWAN		
RUTHERFORD		
SWAIN		
TRANSYLVANIA		
VANCE		
WARREN		
WAYNE		
WILSON		
YADKIN		
YANCEY		

It can be observed that seasonality (high and low) are significant in North Carolina and is spread across the counties. A smaller county such as New Hampton has a high seasonality as compared to a larger county such as Columbus, which highlights the need for addressing the seasonality at the local level. It is essential to list the counties with high and low seasonality and utilize the data to plan for resource allocation and public services adequately. Table 12 can be useful while sorting out the counties that need additional resources for a certain period (counties having seasonality) or the ones that require year-round attention (counties with no seasonality). The study also lists the maximum season in a year for each county in Appendix F to break down the seasonality at more local level.

5.3.2. REGIONAL LEVEL

The counties are sorted in the respective geographic regions and the seasonality is assessed at the geographic region to find out if the variation exists at the regional level. The count of counties having high, low and no seasonality is shown in Table 8 and it can be concluded that Coastal Plains experience the highest seasonality followed by piedmont and mountains. Overall, the seasonality exists in all the regions and hence, it is important that more attention and resources be dedicated towards the regions for a specific period of the year. It highlights the importance of the concept of seasonality.

Table 12: Seasonality at regional level

Coastal Plains	
Seasonality	Number of Counties
High Seasonality	19
Low Seasonality	16
No Seasonality	6
Mountains	
Seasonality	Number of Counties
High Seasonality	16
Low Seasonality	2
No Seasonality	5
Piedmont	
Seasonality	Number of Counties
High Seasonality	12
Low Seasonality	15
No Seasonality	9

Table 8 summarizes the seasonality in each geographic region. It can be observed that the coastal plains have a higher number of counties as compared to mountains and piedmont region and also higher percentage of high and low seasonality to no seasonality. Even though coastal plains have more number of counties, proportion of high to low seasonality in mountainous region is the highest.

5.3.3. STATE LEVEL

The seasonality is assessed at the state level to evaluate the impact of seasonality at a broader level. Almost half of the state experiences high seasonality and 20% of the state does not experience seasonality at all. The concept of seasonality can be observed at all the levels of the state and is crucial to address.

Table 13: Seasonality at state level

North Carolina	
Seasonality	Number of Counties
High Seasonality	47
Low Seasonality	33
No Seasonality	20

CHAPTER 6: SUMMARY, CONCLUSIONS AND RECOMMENDATIONS

This section summarizes the purpose, methodology, and results of the research study. The findings and limitations direct the discussion of the conclusions. Additionally, the recommendations are stated considering two scenarios: (i) related to the contribution of research in the existing literature and (ii) for the researchers interested in extending the scope and findings of the study.

6.1 SUMMARY

Over the years, there is a significant increase in the number of temporary residents in the United States of America. Hence, their positive and negative impacts have always remained a matter of interest for the researchers. Even though the concept of temporary residents is not recent, very little is known about their number, types, characteristics, timing, origins and destinations.

The unavailability of extensive and reliable data related to the seasonal population makes it difficult to predict. That is why the planning process and policies in an area affected by the seasonal population are not that accurate and efficient.

The research study applied a tax-based methodology to account for seasonality in the state of North Carolina. A unit of measurement named “equivalent residents” was defined to express the resident equivalencies in terms of permanent residents. The study assessed the equivalent residents in the state of North Carolina by counties over the period of 5 fiscal years (2012-2016) by the NC Department of Revenue on monthly basis and further are sorted by seasonality. Article 39 Local Sales and Use Tax collections were utilized, and the peak periods of equivalent residents’ visitation were also calculated.

The findings and discussions concluded that seasonality does exist in North Carolina and hence, it is beneficial to evaluate seasonal equivalent residents. It will also prove useful while planning the resource allocation and adjusting existing policies like the Powell Bill according to which the NCDOT makes State Street-Aid allocations to incorporated municipalities to provide funds for improving streets that are not part of the State highway system. The study will provide the much-needed seasonality aspect to be incorporated in the Powell Bill. The peak periods and seasons are also established in the results section to identify the regions which need attention.

6.2 CONCLUSIONS

The purpose of the research study was to develop a methodology to account for seasonal equivalent residents' shifts in North Carolina. Several methods were investigated and after careful deductions, a tax-based methodology was adopted to fulfil the purpose of the study.

The theoretical literature review allowed for a better understanding of the definition, the existing problem and the benefit of estimating the seasonal population. The research gaps were identified, and the objectives were fulfilled in order to contribute to the pool of existing information about the seasonal residents and its impact on the social, political and environmental aspects in a certain area. The developed methodology provides insights into the existence, variability and patterns of seasonal equivalent residents in North Carolina.

The conclusions and their brief discussions drawn from the results section are mentioned below:

Conclusion 1: 80% of the counties in North Carolina experience seasonality

It is noted that 47% of the counties in North Carolina were identified as the ones experiencing high seasonality and 33% as low seasonality indicating that seasonality does exist in North Carolina. It can be concluded that North Carolina has 80% of the counties undergoing seasonality inferring that the population influx of equivalent residents is encountered for a particular time of the year. The region with highest number of counties having seasonality was found to be the Coastal region followed by the Piedmont and Mountains. Hence, these regions require adjustments in the planning and allocation of the resources according to popular seasons to avoid any complications.

Conclusion 2: The magnitude of population influx of equivalent residents is significant

The average proportion of monthly equivalent residents to the permanent residents throughout the state over five years is 0.11. Figure 2-7 in the results section of the study indicate that there is a set pattern followed by the equivalent residents throughout the five-year period. The maximum number of counties have the proportion of average monthly equivalent residents to permanent residents between 0-10%.

A significant proportion implies that the population influx experienced by the state needs to be addressed and estimated year by year to counter the negative impacts by excess population such as, water scarcity, traffic congestion and inefficient distribution of funds.

Conclusion 3: The average monthly equivalent residents are inconsistent throughout the region from 2012-2016

Figures 8, 9 and 10 depict the number of average monthly equivalent residents, and they are not consistent throughout the year. The maximum number of average monthly equivalent residents are experienced by piedmont region followed by coastal plains and

mountains. Even though the magnitude of population influx in the mountains is less, it is more significant when compared to the population of permanent residents in the region.

Conclusion 4: The maximum equivalent resident's population influx is experienced in tourist places

The two main counties having maximum proportion of average monthly equivalent residents are Currituck and Hyde which lie at the extreme point of coastal plain and having wildlife reserves which are one of the main attractions for visitors. It can also be observed that the mountainous region also experiences huge population influx of equivalent residents because of the geographic location.

Additionally, specific limitations were identified in the research study that need to be addressed. One of the major limitations is the assumption of similar expenditure patterns for permanent and equivalent residents giving rise to ambiguity in the number of equivalent residents. This is the reason it is iterated repeatedly in the study that the equivalent residents are a unit of measurement and does not directly signify the visitor population in the state.

The other limitation is that the study might not apply to all the states of the United States due to varying tax collection methods but can undoubtedly be used as a base for utilizing the available tax database. Defining the seasonal population accurately is also a difficult task, and there is no specific way to resolve the issue. Therefore, the study coined a unit of measurement referred to as equivalent residents to prevent any confusion.

It is also not included in the scope of the study to assess the monthly seasonal population at the municipality level. Thus, even though the study cannot predict the seasonality at the most local level, it still addresses all the issues related to seasonal

variations in the state. The data at the county level is accurate and readily available every month resulting in effective estimation.

6.3 RECOMMENDATIONS

The recommendations section presents the suggestions considering the following two scenarios:

- Contribution to the existing literature
 - a) The research study recommends acknowledging the extent and impacts of seasonal residents and the importance to adequately assess them throughout the country.
 - b) The peak influx patterns in North Carolina should be utilized by the planning committees and authorities to address and resolve the issue in the state.
 - c) The findings can also act as a base to modify the tax allocation process by the NCDOT for improving the maintenance procedure of roads and streets.
- Future research studies

This study provided the first step to estimate the seasonality in terms of equivalent residents and further concludes the seasonality in the state. Even though seasonal variations are addressed and derived, the total number of visitor population was not included in the scope of the study. Additional studies could:

- a) Assess the number of visitors
- b) Calculate the population influx at the municipality level
- c) Modify the methodology to predict the seasonal population trends for the next few years.
